# Deer Browse Resources of the Atomic Energy Commission's Savannah River Project Area

by

**William H. Moore**

**Wildlife Biologist**

A procedure developed in Georgia<sup>1</sup> <sup>2</sup> was used to inventory the browse resources of the Atomic Energy Commission's Savannah River Project Area near Aiken, South Carolina. Through this procedure, the forest land manager is supplied with relative carrying capacity data for deer. If silvical practices can be related to habitat quality and quantity, he can adjust management procedures to improve wildlife habitat as well as timber.

The 200,831-acre Savannah River Project Area is located in Aiken, Barnwell, and Allendale Counties, a section of the Atlantic Upper Coastal Plain just south of the "fall line" known as the sandhills. Topography is rolling and deep sandy soils predominate. Two major drainages run through the area and flow into the Savannah River, which runs along the area's southwestern boundary. Approximately 33 percent of the area was under cultivation prior to establishment of the Project during the early 1950's.

Table 1. --Acreage distribution by land class, AEC, Savannah River Project Area

Land class	Acres
Forest lands sampled	172,563
Forest lands not sampled <sup>1</sup>	7,501
Total forest lands	180,064
Nonforest lands, usable by wildlife	6,646
Total usable wildlife habitat	186,710
Other lands	14,121
Total land area	200,831

These are baldcypress-tupelo sites of the Savannah River Bottom not sampled because of high water.

Presently, the Project Area includes 186,710 acres of usable wildlife habitat (table 1). Of this, 180,064 acres are classed as forest lands, with the remainder being primarily open fields and rights-of-way. The additional 14,121 acres include building sites, water surfaces, and other areas unavailable or nonusable by wildlife,

Ripley, Thomas H., and McClure, Joe P. Deer browse resources of north Georgia. Southeast. Forest Exp. Sta., U. S. Forest Serv. Resource Bull. SE-2, 20 pp. 1963.

<sup>2</sup>This study was conducted by the Southeastern Forest Experiment Station in cooperation with the Savannah River Project of the Atomic Energy Commission and the National Forests in South Carolina.

A description of major types sampled in the area follows:

1. Pine plantations. -- Longleaf, slash, and loblolly pines planted mostly in old field sites, but including some direct seeding of longleaf in scrub oak sites. Approximately 4,000 acres were planted by private landowners prior to acquisition by the Atomic Energy Commission. The balance was planted or seeded since 1952.
2. Longleaf pine (natural). - - Longleaf pine predominates. On drier sites, common associates are turkey oak, blackjack oak, bluejack oak, scarlet oak, and dwarf post oak. In the branch heads, loblolly pine, hickories, sweetgum, and southern red oak occur.
3. Loblolly pine (natural). --Principal associates are sweetgum, oaks, and hickories on well-drained sites, and spruce pine, yellow-poplar, shortleaf pine, blackgum, and water oak on the poorly drained sites.
4. Longleaf-scrub oak. --These dry sites contain mainly turkey oak, blackjack oak, bluejack oak, scarlet oak, and dwarf post oak, associated with remnants of the former longleaf pine stand.
5. Loblolly-scrub hardwoods. --These are fairly fertile moist sites, with a mixture of water oak, willow oak, blackjack oak, post oak, persimmon, hickories, and blackgum. This type occupies mostly former loblolly pine and loblolly pine-hardwood sites.
6. Pine-hardwoods . - -Loblolly pine is the key species and occupies at least 25 percent of the stand. It is associated with a wide variety of moist site hardwoods, such as sweetgum, yellow-poplar, sweetbay, blackgum, swamp white oak, swamp chestnut oak, and cherrybark oak.
7. Bottomland hardwoods. --This type includes a wide variety of wet sites, the bulk of which occurs along the Upper and Lower Three Runs Drainages and the Savannah River Bottom. Common species are swamp chestnut oak, swamp white oak, cherrybark oak, sweetgum, blackgum, yellow-poplar, red maple, green ash, sycamore, black willow, and cottonwood.

### Methods

Fifteen overstory characteristics were chosen as strata for sampling, using existing continuous forest inventory plot data. Each stratum (table 2) was sampled at 20 to 30 locations each for a total of 380 locations, or 3,800 plot samples. Sampling was done during the 3-month period, December 1963 through February 1964.

Table 2. --List of overstory classes sampled showing codes and number of locations in each class

Overstory class	Code number	Locations
		<u>Number</u>
<b>I. Plantations (longleaf, slash, loblolly)</b>		
A. Nonthinned		
1. 0-6 years old	01	30
2. 6+ years old	02	30
B. Thinned (6+ years old)	03	30
<b>II. Natural stands</b>		
A. Longleaf pine	10	30
B. Longleaf-scrub oak	20	20
C. Loblolly pine		
1. Seedlings and saplings	31	30
2. Poletimber and sawtimber	32	30
D. Loblolly-scrub hardwoods	40	30
E. Pine-hardwoods	50	30
F. Bottomland hardwoods		
1. Below 200 feet elevation (Savannah River Bottom)		
a. Seedlings and saplings	81	20
b. Poletimber and sawtimber	82	20
2. Above 200 feet elevation		
a. Upper Three Runs Drainage		
1. Seedlings and saplings	83	20
2. Poletimber and sawtimber	84	20
b. Lower Three Runs Drainage		
1. Seedlings and saplings	85	20
2. Poletimber and sawtimber	86	20
Total		380

Three specific attributes of the browse resource--species occurrence, utilization by deer, and browse weight--were measured on a cylindrical plot, 1 milacre in area and  $4\frac{1}{2}$  feet high, at each of 10 systematically arranged points for each sample location. At each point, all woody plants within the plot were recorded by species (up to 10), and each species was assigned one of the four browse preference rankings:

#### Desirables

1. Preferred--Delicacies or "candy" species. These are usually highly nutritive and are the first species consumed by deer.
2. Staple- -Foundation or "bread and butter" species. These constitute the bulk of deer diet on good range. They are high in nutritive value and provide for normal animal weight gain and reproduction.

### Undesirables

3. Emergency -Life-sustaining species. These provide a large part of the diet on overstocked ranges. They are generally low in nutritive value and produce little or no animal weight gain, and animal reproduction is usually low.

4. Stuffing -Starvation species. These plants have little or no food value. Animals continually lose weight and animal **reproduction** is very low, if they are a major part of the diet. Some may even be toxic.

Browse weight of each species was then estimated and the presence or absence of use by deer was recorded. Weight of browse present in the cylindrical plot in terms of pounds of dry browse per acre available during the winter period was estimated with the aid of photograph standards (see footnote 2). Estimates were made to the nearest 10 pounds per acre. Control checks of estimates were made by clipping at least two plots weekly, but more often when needed, to maintain crew accuracy of estimates within 10 percent of clipped weights. The total **number of** woody species occurring in each plot was also recorded.

In addition, three overstory variables were measured **from each** plot: (1) Basal area, (2) height of the nearest dominant tree, and **(3) species** of the dominant tree. All plot data were summarized by preference class, averaged for the location, and viewed as a single observation (cluster sample). Frequency of occurrence, percent utilization, and browse weights were examined for differences between major types, stand sizes, age classes, and various type combinations by standard analyses of variance computations. Characteristics of the understory and the overstory were examined for significant relationships. Basal area, overstory height, and time of survey were used as independent variables in standard multiple regression analyses.

### Results and Discussion

The multiple regression analyses of various expressions of basal area, height, time of survey, and transformations thereof (**X** variables) in combination with frequency occurrence, weight, and degree of use of the various browse classes (**Y** variables) yielded no significant or meaningful relationships. These same understory observations were examined for differences between various combinations of overstory attributes by analysis of variance. These results, as expected, were meaningful, and are presented in the appendix, together with probability statements and confidence limits.

Summaries of plant occurrence, browse weight, and degree of use are shown in tables 3, 4, and 5. Generally speaking, the better sites contained more desirable species and greater weight of desirable browse. For example, the bottomland sites contained many more desirable species than the drier upland sites. Desirable plants, however, occurred less frequently in plantations than in natural stands. A similar pattern existed for desirable browse weight.

Overall, very little browse utilization was in evidence on the Project Area. Nevertheless, some use was noted throughout the area, particularly in the bottomlands and adjacent sites. Apparently, higher browsing pressure and more favorable browse supplies are both associated with the better hardwood sites.

It has been assumed that approximately 625 pounds of desirable browse are required to support an average white-tailed deer over winter (see footnote 2). By using browse weights shown in table 4, the approximate carrying capacity values for the overstory classes sampled were calculated and are shown in table 6. Based on these figures, the approximate carrying capacity for the area would be between 5,000 to 6,000 animals. This, of course, does not include other foodstuffs, such as mast or dry fallen leaves, or old field and roadside greeneries, such as winter rosettes and Japanese honeysuckle. The latter is especially abundant and actual optimum carrying capacity may be more like 8,000 to 10,000 animals.
